## PREFACE.

have been established by the experience of almost a century, yet very little has been done to ascertain their particular nature. The account given by Dr. Brown in his history of Jamaica, as well as that in the history published in 1774 (which are the only ones that I have ever seen) are both not only defective, but extremely erroneous. What may have been done by my predecessors, or others, in the investigation of these waters I am totally unacquainted with, as their experiments have never come to light:

I hope therefore that my humble attempts may not be unacceptable to the public.

Although the chemical analysis of mineral waters may not be adequate to a full explanation of their virtues and effects, yet it certainly tends to throw considerable light on their operation, and to direct to a more safe, certain, and beneficial application of them. It is even useful to know what a mineral water does not contain, as will be seen from the mistaken notions that have been entertained concerning the waters here treated of.

To make the subject universally intelligible, I have, in an introductory part, given a few chemical sketches relating to it; in which I can pretend to no novelty or merit, unless from the mode of arrangement, and from having avoided, as much as possible, technical obscurity.

I might have enlarged much more than I have done upon the uses of the Bath waters, but it would have been impossible to particularise diseafes and fymptoms with fo much nicety, as to preclude the necessity of advice, or make a book ferve the place of a physician; but I presume I have faid enough to shew their extensive utility, and to explain in fome degree their nature and operation. Could I have told how to make the publication more useful, and more deserving of the liberal patronage it has met with, no pains should have been wanting; but having done my best, I have only to add my grateful acknowledgments, and to pray that the most favourable construction may be put on my endeavours.

## CONTENTS.

### I. Of the Introduction.

- DECT. 1. On Chemical Bodies and their Affinities.
  - 2. On the Impregnations, or Contents, of Mineral Waters in general.
  - 3. On the Methods of examining and analysing Mineral Waters.

### II. Of the Differtation.

- SECT. 1. History and Analysis of the Bath Waters.
  - 2. The Use and Administration of the Bath Waters in the Cure of Diseases.

## INTRODUCTION;

CONTAINING

A short Essay on Mineral Waters.

#### SECTION I.

INERAL WATERS constituting a very useful branch of the Materia Medica, have from the earliest ages engaged the attention of mankind: As they are various in their nature they afford a remedy for various disorders, but are particularly beneficial in complaints of the chronical kind, where all other medicines frequently fail. The improvements which have been

lately made in chemistry have enabled phyficians fo fully to explore and afcertain the nature of many of the mineral waters, as to imitate them with great exactitude; and, as fome of them owe their efficacy to a volatile principle that fuddenly escapes notwithstanding every means that can be made use of to detain it, the \* artificial impregnations of . waters may in a few instances be preferable to those formed by nature; that is, when they cannot be used on the spot, or where they cannot be obtained in a perfect state, viz. without having previously suffered some change, if not loss of their properties: But, in general, nature prepares this class of remedies much more perfectly in her laboratory than the chemist can do in his; for though we may by analysis detect the several principles of a mineral water, yet we cannot always again

<sup>\*</sup> Should any of my readers be desirous of being instructed in the method of preparing the mineral waters artificially, I must beg leave to refer them to Dr. Priestly, or to a late pamphlet by Dr. Elliot, in which is explained the particular manner of imitating almost all the most useful mineral waters, whether saline, chalybeate, or sulphureous.—The apparatus for this purpose, as invented by Dr. Priestly, and improved by Dr. Naoth and others, may be bought of the different druggists in this issand.

combine those principles in the mode they before existed, and so as to give them the same properties. Mineral waters will therefore ever retain their importance; and as they are, in some diseases of the human body, the most efficacious kind of remedy, so they are at the same time the most agreeable one, and can with less inconveniency or difgust be persisted in, for a due length of time, than any other whatsoever.

Among the great number of mineral waters found in different parts of the world, I may with great fafety affert, that there cannot be a more valuable one than that which is the fubject of this publication, or that possesses greater virtues in the cure of fundry diseases; to make the nature and effects of which better understood, it will be necessary to premise something concerning mineral waters in general, and of the methods made use of in examining them: I hope to explain the subject so as to render it intelligible to those who have never before studied it, and have no previous acquaintance with chemistry; in order to which,

we must take a slight \* survey of chemical bodies, and of their several affinities or relations to each other.

### A General View of Chemical Bodies.

LL the bodies in nature, confidered in relation to their chemical properties, are divisible into fix classes, viz.—1. Salts,—2. Inflammable Substances,—3. Earths and earthy Substances,—4. Metals and metallic Substances,—5. Water,—6. Air and aerial Substances.

### I. SALTS.

THESE are defined by Chemists to be fufible with heat, fapid in the mouth, and foluble in water; but the two last mentioned pro-

<sup>\*</sup> The fcience of chemistry has such an extensive connection with the arts, and with the other branches of natural knowledge, that I flatter myself the following outlines may be useful not merely in relation to mineral waters, but to many other subjects that require investigation—as, the process of sugar boiling, distillation of rum, manufacture of indigo, manufacture of pot-ash, &c. &c. all which depend directly on chemistry, and certainly require some share of chemical knowledge.

perties, constitute their most general character. It is not necessary in such a sketch as this to study much precision; I hope therefore the chemists will not complain of my definitions being inaccurate and incomplete.

The following table exhibits a general view of falts, and requires only a fimple infpection to be perfectly understood.

### TABLE OF SALTS.

I. SIMPLE.

1. Acid. 

Fossile. 

Vitriolic, viz. Oil of Vitriol Nitrous, — Aqua Fortis Muriatic, — Spirit of Salt Vegetable. 

Vegetable. 

Acetous, viz. Vinegar Tartarous, — Tartar

Vegetable, viz. Pearl Ashes Smild or Salt of Tartar Caustic Fossile, — Barilla

Volatile. 

Volatile. 

Volatile. 

Volatile or Sal. Volatile Caustic

#### II. COMPOUND.

1. Neutral, composed of Acid and Alkali.

2. Earthy, composed of Acids and Earths.
3. Metallic, composed of Acids and Metals.

The above view of the simple salts, I think, can require no fort of explanation; it is obvious from the arrangement, that they are generically distinguished by being either acid or alkaline; the acid falts are either fossile, or vegetable: Again, the fossile acids are of three kinds, vitriolic, nitrous, and muriatic; the common names of which are subjoined. The vitriolic acid is the fame thing as oil of vitriol; the nitrous acid is aqua fortis, or spirits of nitre; and the muriatic acid is spirit of falt. In the same manner the alkaline falts are divided and fubdivided. By arranging substances in this method, the memory is much affisted, and descriptions rendered unnecessary. I shall proceed to enumerate the other compound falts in the fame manner.

### I. NEUTRAL SALTS.

ARE those which are formed by the union of an acid and alkali; having the properties of neither, but making (as chemists speak) a tertium quid; that is, a new substance sur generis, or of a distinct kind.

The following table exhibits a catalogue of most of the neutral salts, and shews the manner in which they are formed. It is to be thus understood; viz. the vitriolic acid in the first column, combined with the vegetable alkali in the second, makes the neutral salt, in the third column, called vitriolated tartar:—Again, the vitriolic acid, with the fossile alkali in the next line, forms Glauber's salt, &c. &c.

### TABLE OF NEUTRAL SALTS.

ACID. ALKALI. NEUTRAL SALTS.

1. Vitriolic. 

Vegetable, - Vitriolated Tartar
Fossile, - Glauber's Salts
Volatile, - Vitriolic Ammoniac

2. Nitrons. 

Vegetable, - Nitre, or Salt-petre
Fossile, - Cubic Nitre
Volatile, - Nitrous Ammoniac

3. Muriatic. { Vegetable, - Digestive Salt Fossile, - Common Salt Volatile, - Crude Ammoniac

4. Vegetable. { Vegetable, - Diuretic Salt Fossile, - Rochelle, or Seignette do. Volatile, - Spir:ts of Mindererus

# Table of Juch Earthy and Metallic falts as are found in Mineral Waters:

I. WITH THE VITRIOLIC ACID, AND

	Calcareous	earth,	Selenites, or Gyp-
1. Earths.	Magnefia,		S Epfem Salts, or bit-
	Clay or par	rticular	earth, = Allum
	(7:na	-	White Vitriol
2. Metals	(Iron,	ma .	Green Vitriol
	Copper,	-	Blue Vitriol

II. WITH THE NITROUS ACID, AND Calcareous earth, - Calcareous nitre. (doub ful)

Calcareous earth, Magnesia, Fixed ammoniac.

I have judged it needless in this place to enumerate any of the metallic salts, except such as are sound in waters, and of which it was proper to know the composition. The next general class, is that of

### II. INFLAMMABLE SUBSTANCES.

THESE are such bodies as (without any definition) are known to take slame and confume with heat. Under this head are in-

cluded all oils, refins, fulphur, ardent fpirits, &c.

The inflammability of bodies depends on a principle they contain called by chemists phlogiston; which principle exists in all bodies, but in different quantities and in different states of combination; whence their difference in respect of inflammability and various other properties. So many phenomena in nature depend on this pervading principle, that the study of it constitutes a main branch of chemical philosophy. We shall see hereaster what connection it has with the subject of mineral waters, but at present we need take no further notice of it.

### III. METALLIC BODIES.

THE well known properties of these are their great specific gravity and sussibility with certain degrees of heat. All the metals contain a great portion of phlogiston; deprived of which they lose their metallic form, and are reduced to a fort of earth called calx,—thus e. g. cerusse is the calx of lead.

The metals, in their fossile state, are found in various forms:

1. Virgin or pure.

2. In ores combined with earths.

3. Mineralized with fulphur and arfenic

4. Diffolved by acids or by other means, and mixed with mineral waters.

### TABLE OF EARTHS.

#### I. ABSORBENTS.

The character of these is their effervescence with acids: they are of two kinds:

- 1. Calcareous, viz. chalk, &c. which convert by heat into quick-lime, and become caustic. This is effected by the expulsion of fixed air; which as soon as they imbibe again they lose their causticity and become mild.
- into quick-lime, or become caustice as the preceding.

#### II. CHRYSTALLINE OR FLINTY.

These are hard and strike fire with steel: are either

- 1. Apyrous, i. e. indestructible by heat as some of the precious stones, or
- 2. Vitrescent or fusible, running by heat into glass; such are common slints, fand, &c.

#### III. ARGILLACEOUS,

Or Clays, which do not effervesce with acids, nor melt into glass, but are unchangeable in the fire.

#### IV. MICACEOUS.

Stones of a shining laminated or sibrous texture. They do not effervesce with acids, nor strike fire with steel, but are either

- 1. Talcky, which in a strong heat are vitrescent, or
- 2. Asbertos, Amianthos, &c. indestructible by heat.
- N. B. Gypfum and gypfeous marters, which are fometimes confidered under the

head of earths, are more properly earthy falts. (Vid. table of earthy falts)

Spars are stones of very different natures, and arrange under absorbent earths, micaceous earths, &c.

Marles are absorbent earths.

## V. WATER.

THE properties of water are too well known to require any description. Pure elementary water is hardly to be obtained, but it may be considered either as such, or else impregnated with foreign matters, as, particularly, in mineral waters.

### VI. AERIAL MATTERS.

AIR, as well as water, has by all philosophers been considered as an elementary substance; but this seems to be brought into some doubt by the late celebrated experimenters in chemistry, who have discovered many species of air, and distinguish that by which animal life is supported, as atmosphe.

ric or respirable air: The other kinds more particularly deserving of note are,

- 1. Fixed or mephitic air +.
- 2. Phlogisticated air, which is either
  - 1. Inflammable, taking fire, or
  - 2. Non-inflammable, extinguishing flame.

These kinds of air are variously produced, and exhibit wonderful phenomena; but this is not a place to enter into any further consideration of that curious subject. \*

Having now pointed out the general and distinguishing characters of the several classes of chemical bodies, I shall proceed to explain the affinities of these, or the relations which they have to each other; upon which depend all the processes in chemistry, as well as many of the most important operations in nature.

<sup>†</sup> Mephitic Air is demonstrated to be an Acid.
(Vid. Bewley apud Priestly.)

<sup>\*</sup> Vid. PRIESTLY and others.

# On Chemical Affinities.

HE affinities of bodies fignify their disposition to unite, or the attraction they have for each other, which is owing to fome unknown relation between them: this attraction is greater between some than others, and is therefore called elective: - For example, acids have an attraction both for alkalies and absorbent earths, but a much stronger attraction for the former than the latter; in consequence of which, if an abforbent earth be first dissolved in an acid. and afterwards an alkali be added, the acid having a greater affinity to the latter will unite with it and deposit the earth. Again, acids in general have a greater attraction for earths than for metals, fo that if you add an earth to the folution of a metal in any acid, the metal will be precipitated, It is in this way that various combinations and decompositions are effected, and that we are enabled to analyze bodies and detect their principles. I need not here give any further illustration of the subject, as the application of it to the investigation of mineral waters,

which this is intended to explain, will exhibit a perfect view of it. All that is further required in this place, is, to point out the known laws of affinities, as they have been discovered in the course of experiment and in the practice of chemistry: these have been reduced into tables: the following one is the most approved, as being corrected by some of the greatest philosophers of the age.

The table is thus to be understood, viz. Under the head of acids is placed, first, phlogiston, then alkali mild, &c. the meaning of which is, that acids have an attraction for those different substances according to the order in which they are placed, i. e. they have a greater attraction for phlogiston than alkalies, for alkalies than absorbents, earths, &c.

### Table of Affinities or Elective Attractions.

#### I. ACIDS IN GENERAL.

2. Fixed alkali; calcareous earth
 caustic mild 4. Magnesia

5. Calcareous earth mild mild
6. Volatile alkali 9. Earth of alum caustic 10. Pure or precious 7. Metallic substances in general metals.

#### 2. VITRIOLIC ACID.

Vid. acids in general.

1. Zinc
2. Nickell
3. Cobalt
4. Iron
5. Copper

6. Silver
7. Tin
8. Lead and Mercury
9. Volatile Alkali
10. Earth of Alum
5. Copper

#### 3. NITROUS ACID.

Vid. acids in gen.

1. Zinc
2. Lead or Tin
3. Iron
4. Bifmuth and Antimony

5. Copper

### II. METALLIC SUBSTANCES in general.

Muriatic acid Vitriolic acid Nitrous acid Phlogiston Fixed air

## 12. GOLD, —Aqua regia

### 13. SILVER.

Muriatic acid Vitriolic acid Nitrous acid Lead, Copper

#### 14. MERCURY.

Muriatic acid Vitriolic acid Nitrous acid Gold Silver Lead, &c.

#### 15. IRON.

Vitriolic acid Muriatic acid Nitrous acid . Regulus of antimony

#### 16. COPPER.

Vitriolic acid Muriatic acid Nitrous acid Vegetable acid

I flatter myself that the preceding sketches are sufficiently intelligible to every reader who may think it worth his pains to give the slightest attention to them; and that they will serve to render what follows on Mineral Waters easily comprehended.

#### CHAPTER II.

On the CONTENTS of MINERAL WATERS.

S this is not a work intended for the perufal of the learned, I do not think it requisite to enter largely into the investigation of the subject, but shall content myfelf, according to the plan I set off with, in giving a plain and easy introduction to it. Such of my readers as may be induced to study it more fully, and to extend their refearches into this pleasing and useful science, must have recourse to other authors; amongst whom I would particularly recommend Dr. Faulkener, one that in this part of my work I am particularly indebted to.

The list of matters contained in mineral waters was formerly much larger than at present, later experience having demonstrated the impossibility of many impregnations supposed by the old chemists, particularly the nitrous and ammoniacal salts, of which we find so frequent mention in former writers: The acids of these salts have never (like the vitriolic) been found separate, and

if they were, they would still want a proper base, as neither the vegetable or volatile alkali have ever been discovered in a fossile state.

TABLE exhibiting the several Contents of MINERAL WATERS.

#### I. SALTS.

1. Acid, - Vitriolic in a separate state.

2. Alkali, - Fossile Alkali.

2. Neutral, - Glauber's Salt, Common do.

#### II. INFLAMMABLES.

#### I. FOSSILE OIL, viz. PETROLEUM.

1. Separate, or float- 2. Combined with an Alkali in form of ing on the furface of waters. a Soap.

#### 2. SULPHUR.

1. Per se, diffused or 3. Combined with fuspended.

2. Combined with in a caustic state,
Alkali, forming forming Calcareous
Hepar Sulphuris.

Calcareous Earth
in a caustic state,
forming Calcareous
Hepar Sulphuris.

#### III. EARTHS and EARTHY SALTS.

#### I. CALCAREOUS EARTH.

r. In a caustic state, ed Air. or deprived of fix- 2. Combined with

the Vitriolic Acid, forming Selenites. 3. Combined with

Sulphur, forming Hepar Sulphuris.

### 2. EARTH OF MAGNESIA dissolved.

1. By Vitriolic Acid, 2. By Muriatic Acid, forming Epsom Salts.

constituting a Salt that has no name.

#### 3. EARTH OF ALLUM.

Forming with Vitriolic Acid the Salt of Alum

#### IV. METALLIC MATTERS.

I. COPPER dissolved.

Blue Vitriol. By the Vitriolic Acid in the form of

### 2. IRON dissolved.

form of Green Vit. 1. By Fixed Air. 2. Vitriolic Acid in 3. Hepar Sulphuris.

3. ZINC dissolved.

Vitriolic Acid, in form of White Vitriol.

#### V. AERIAL MATTERS.

1. Common, or atmospheric Air, 2. Mephitic, or fix-

ed Air. 3. Phlogisticated, or inflammable Air.

The above table comprehends, on the authority of the best Chemists, all the known impregnations of mineral waters. Many other matters, as I have faid, were formerly included; but I suggested the reason why in particular the nitrous and ammoniacal falts cannot have an existence in mineral waters. For fimilar reasons none of the metals, except Iron, Copper, and Zinc, are ever found in waters, viz. because there are no fossile menstrua capable of dissolving them, the vitriolic acid and hepar fulphuris not acting on the other metals except by the affistance of heat, or under some other circumstances that are not supposed to take place in the bowels of the earth.

Arsenic has however, in particular, been conjectured to be present in some waters; but in the opinion of the best authors, this poisonous semi-metal is only soluble in water when deprived of its phlogiston or sulphur, in which state it cannot be found in ores.

The existence of an \* actual Sulphur in waters has been long questioned, but it seems on very good evidence, as we shall see when we come to the manner of analysing waters, to be really found in some sew of them. The aerial impregnations of waters are of late discovery, and have thrown an entire new light upon the subject, as they account for several combinations among the fixed matters, as well as for the medicinal efficacy of many of the waters of principal note.

I shall here subjoin a catalogue of the most important mineral springs in the various parts of the globe, with a summary of their contents, according to the latest and most approved analysis; which may serve not only to gratify curiosity, but to convey a general idea of their medicinal qualities and uses in the cure of diseases.

<sup>\*</sup> Some chemists have supposed the Sulphur found in mineral waters did not exist in the waters as a sulphur, but is formed afterwards by a new union of the component principles.

# CATALOGUE OF THE MOST CELEBRATED MINERAL WATERS.

Aix-la-Chapelle.—Those Waters contain an actual Sulphur, and are very hot.

Bath (English) Waters.—Contain fixed Air, phlogisticated Air, Hepar Sulphuris with Quick-lime, and a little Iron—

Vid. Faulkener, Nooth, Priestly.

Bath (famaica) Vid. Analysis following. Barcges.—Hepar Sulphuris, Bitumen, and Sea Salt.

Buxton.—Similar to Bristol.

Bristol.—Calcareous Earth, marine Salt, and fome Sulphur. Vid. Elliott.

Caroline Baths (in Germany).—Pure alkaline Salt, calcareous Earth, and a little Iron.

Vid. Hoffman.

Cheltenham. — Epsom, or bitter purging Salts. Vid. Lewis.

Hartfell.—Martial or green Vitriol in confiderable quantity.

Lewis.

Islington. - A Chalybeate Water.

Moffat (in Scotland). — Sulphur and marine Salt. Plummer. Mosfat (in famaica).—The same as the above.

Vid. Analysis by Dr. Mitchell.

Pyrmont. — A great deal of fixed Air, by which Iron is diffolved in it. Brownrigg.

Spa.—Fixed Air, Ocher, Sulphur.

Sedlitz (in Bohemia). — Epsom or purging Salts.

Teplitz (in Germany).—Is a Spring of pure hot Water. Hoffman.

Tilbury.—Alkaline Salt. Lewis.

Wicklow (in Ireland). — Copper, or blue Vitriol.

Smith's (in famaica).—A martial Vitriol, like the Hartfell Spa. Dr. Clarke found that it is also impregnated with fixed Air, and suspects the Iron to be kept diffolved by this as well as the Acid.

ing point.						
* Musq. Sh. Waters, near the boiling point.						

<sup>\*</sup> I am informed by my friend Major Lawrie, Superintendent of the Musquito-shore, (a Gentleman well known for his active services in the defence of that valuable country, where he resided many years, and employed a very attentive observation on every useful and curious object,) that so great is the heat of this spring that either animal or vegetable substances, placed in the reservoir into which it runs, are in a moderate space of time rendered sit for use, and that the Indians accordingly frequently dress their sood

in it. It appears nevertheless to contain no mineral impregnation.

Of the Method of Analysing Mineral Waters.

IT has been before remarked, that there is no water to be obtained perfectly pure. That which is most free from impurities is snow water, next rain water \*, and then the waters of limpid rivers; but they all contain more or less of earthy and saline matter, even after repeated distillations, which has favoured the hypothesis of the ancient philosopher, that earth and all things were formed of water.

The first thing to be attended to in the examination of any water is not its pellucidity, or apparent purity, but its weight, the purest water being always the lightest. The gravity of water is ascertained either by weighing a certain measure of it in a well adjusted pair of scales, or by the water possecalled the hydrometer. Where proper scales

<sup>†</sup> A suspicion has been entertained, that the rain water of this country contained vitriolic acid; to determine this I collected some in a glass vessel during a heavy shower, which I tried with the solutions of silver, lead, and mercury in the nitrous acid;—With the first, there appeared a light purple tinge, which at length became reddish; with the lead it dropped a white precipitate, and the same with mercury, which I allowed to remain for 24 hours, without observing any change to yellow, as should have happened had there been any vitriolic acid present.—Vid. page 16.1

and weights, or the above inflrument cannot be procured, another method has been proposed for comparing the relative weight of the water of any mineral spring with the other waters in the neighbourhood, viz. by tincturing the water with saffron, or any other colouring matter that makes but little addition to its own weight, and then inserting the bottle filled with it in a vessel of the water you want to compare it with. If the coloured water is specifically heavier than the common water, it will of course run out and communicate a tincture to the water in which the bottle is immersed.

Table of the Weights of different Waters.

06 110111 1		Oz.	Dr	Gr.
Of distilled water,		15	I	50
Rain water,	ditto	15	2	40
Spring water,	ditto	-		129
Sea water,	ditto	15	5	20

After having ascertained the apparent and sensible qualities of any water with its relative weight to other water, or to pure water, we may proceed to try it by some of the most ordinary and general methods, as follow:

- 1. If it lathers well with Soap.
- 2: If it curdles milk.
- 3. If it effervesces on the addition of acid or alkali.
- 4. If it changes the colours of blue flowers, infused in it for some time, either to red or green.
- 5. If it turns milky on adding to it a few drops of any of the following folutions, viz.
  - ver of fulphur,) in water.
  - 2. A folution of faccharum faturni, (i.e. fugar of lead,) in distilled water.
  - 3. A folution of lead in aqua fortis.
  - 4. A folution of filver in ditto.
  - Or, lastly, if it strikes a black or purple colour with the powder or tincture of Galls.

By these general trials we can discover not only the degree of purity in a water, but is: it contains any mineral impregnation we can form some probable conjecture as to the nature thereof, to direct us in our further researches. The explanation of the above

modes of trial will be feen prefently as we go on to point out more particularly how the various fubstances contained in mineral waters may be severally detected.

# I. To discover the Aerial Impregnations of Waters.

1. FIXED AIR,—first, gives to waters a sparkling appearance and poignant taste, similar to Champaigne or Perry, which liquors, as well as many others, contain a considerable quantity of it \*.

Secondly, Waters containing fixed air added to lime water precipitates the calcareous earth which was only rendered foluble in water by being deprived of its fixed air.

Thirdly, Waters containing fixed air have the fingular property of diffolving iron.

<sup>\*</sup> Waters containing fixed air are difficultly kept, the bottles bursting; Mr. Shackleford lately returned from the continent of North America, informs me, that, at the famed plains of Saratoga, he faw, in company with his fellow traveller Dr. James, (a gentleman well known for his medical abilities) a mineral water that contained so much elastic air, that bottles only about half filled were broke by it.

II. INFLAMMABLE AIR in waters, as also fixed air, may be collected, by tying an oiled bladder over the neck of a bottle containing the water. Inflammable air is lighter than common air, has a peculiar smell, and takes flame \* when it approaches any burning body.

A more accurate method of trial may be feen in the works of that learned philosopher Dr. Prieftly, to whom I must refer my readers for more ample instruction respecting this and the several other species of phlogisticated air.

To discover an acid in Waters.

THE only acid found in waters in a feparate state (vid. table,) is the vitriolic, and most commonly that species of it called the volatile fulphureous, from the smell, &c. which it has from the phlogiston with which it is combined.

In whatever form the vitriolic acid enters

<sup>\*</sup> The damps of mines are either fixed or inflammable air.

into waters, it may be detected in the following manner:

1. By the infusion of blue flowers in the water, which, if there be an acid, will become red \*.

This last, though a common one, is by itself not decisive, because fixed air and alum in waters will effect the same change.

2. By adding to the water a little alkaline falt, or a few drops of oil of Tartar.

If the acid be present in any quantity, it will excite an effervescence with the alkali.

3. By dropping into the water a tincture of foap in ardent spirits, provided the water contains an acid it will unite immediately with the alkali of the soap, and the oil, which is the other ingredient in the composition of soap, is separated and renders the water milky: This serves to explain the effect of hard waters in general in curdling soap.

<sup>\*</sup> Alkalies turn blue vegetables of a green colour, (vid. p. 17.)

4. By dropping into the water, a folution of hepar sulphuris, which is a combination of sulphur and alkali: The same attraction, where there is an acid, takes place here as above in No. 3; the acid unites with the alkali, and the sulphur precipitated makes the water turbid and milky.

I observed that an aluminous impregnation gives to waters tried in the above manner most of the same appearances as the vitriolic acid in a separate state; but to distinguish aluminous water from those containing an acid, we may,

- I. Repeat the above experiment on the waters after they have stood for some time; if the changes produced were caused by an alum in them, the same result will follow on making the same trials; but the acid of waters being, as was before said, generally the volatile vitriolic, this upon the water standing for some time slies off.
- 2. Waters containing an acid will effervesce with and dissolve magnesia, remaining

perfectly clear, (provided only the necessary quantity of magnesia is made use of,) but when they contain an alum, the addition of magnesia will cause a precipitation, the vitriolic acid having a greater attraction for that than the aluminous earth:

There remains one more test, which serves to discover the vitriolic acid either in a separate or combined state; this is an unfaturated \* folition of lead in the nitrous acid, which being added to any water that contains the vitriolic acid, this acid (viz. the vitriolic) having a greater attraction for lead than the nitrous, (vid. table of affinities, ) unites with the lead in place of the latter, and the fubstance formed by this union, called a plumbum corneum, being not foluble in water, disturbs the transparency of it. It is requifite in the above experiment that there should be a redundancy of acid in the test, to prevent the lead from being precipitated by any calcareous earth the water may at the fame time contain.

<sup>\*</sup> Unfaturated, fignifies, not fo much as the acid is capable of diffolving.

# To discover an Alkali in Waters.

HE alkali found in mineral waters we have said is always the fossile, the vegetable being generated only on the furface of the earth.

An alkali in waters is discovered,

1. By their turning the blue flowers to a green colour.

2. By their effervescing on the addition

of an acid.

3. By their precipitating chalk from its solution in aqua fortis.

- N. B. The aqua fortis should be saturated with the chalk, (i. e. contain as much as it is capable of dissolving,) or else the part of the acid that remains unfaturated will diffolve the alkali in the water fo that it will not precipitate the chalk.
- 4. By their precipitating an ochre from folutions of iron in the vitriolic acid, or from a folution of green vitriol in water, the acid of the vitriol having a greater attraction for the alkali than the metal, (vid. table of affinities.)

As the presence of a volatile alkali in waters is not admitted, it is needless to adduce any of the criteria. I shall however, for form's sake, observe, that,

- 1. A folution of corrofive fublimate in diftilled water is precipitated by the volatile alkali in a white, but by the fixed alkali in a red or brown powder.
- 2. If a water contains any quantity of volatile alkali, it will acquire, from copper immersed in it, a fine blue tincture.

To discover the Neutral Salts in Mineral Waters.

#### I. GLAUBER'S SALT.

# THIS falt is known,

- 1. By its taste and the form of its chrystals, which are hexagonal: these may be easily obtained from waters containing it by a slow evaporation till a pellicle forms on the surface, and then placing the liquor at rest for the chrystals to shoot: the addition of a little spirit of wine towards the end assists the chrystallization.
- 2. By the folution of the falt in water coagulating when spirit of wine is added to

it; the spirits attracting a part of the moifture from the salt, it begins to resume its chrystalline form.

- 3. By its fusibility in a gentle heat, which is a property peculiar to this neutral salt.
- 4. By no precipitation taking place on adding an alkali to it when dissolved in water, which always happens to falts with an earthy base, as Epsom salt, &c. (vid. table of affinities.)
- 5. By the precipitation of a yellow powder (i. e. a turbith mineral) on adding a folution of mercury in the nitrous acid, the mercury leaving the nitrous acid to unite with the vitriolic.

## II. COMMON SALT, is known,

- 1. By the figure of its chrystals, which are cubes, and which may be obtained by long boiling, and then placing the liquor to cool.
- 2. By its decrepitation (crackling) on being placed on a hot iron.

- g. By its decomposition and suffocating fumes, on adding either the vitriolic or the nitrous acid, which have a greater attraction for the alkaline base than the muriatic acid, of which it is formed, (vid. affinities.)
- 4. Waters containing sea salt, or the muriatic acid, precipitate lead and silver from aqua fortis, the muriatic acid having a greater attraction for those metals than the nitrous.
- 5. The residuum of waters containing sea salt, added to aqua fortis, constitute an aqua regia capable of dissolving gold: It may be tried with gold leaf, or a mark on the touch slone.

Although the presence of the other neutral salts in mineral waters be so very doubtful, I shall nevertheless point out the characteristic properties by which they may be distinguished.

form of its chrystals,—2d, by its deflagration for manner of purning,—3d, by its turning the flesh of animals red.

- an earthy base, does not deslagrate as common nitre, but blisters, and being subjected to a strong heat, the acid is expelled and the earth converted into quick-lime.—A solution of calcareous nitre is also exposed by the addition of alkali.
- 3. Common ammoniac may be known by its giving out the volatile alkali on adding a fixed one, the acid having a greater affinity for the latter: the volatile alkali is immediately perceived by its pungent vapours when applied to the nostrils.

# To discover Sulphur in Waters.

FEW of the waters which, from their fmell and other properties, have been called fulphureous, contain a real or actual fulphur, but either a hepar fulphuris, or else a fulphureous Gas, (i. e. the phlogiston) in some mode of combination hitherto not very well understood.

Waters that contain an actual fulphur, as it is only fuspended, not dissolved, generally

deposit it about the sides of the vessels or refervoirs in which they are placed; but when present only in a small quantity, so as not to be perceptible in the foregoing manner, the sand or mud of the springs may be dried and thrown on a plate of hot iron; if there be any sulphur contained therein the sumes will presently discover it.

Waters containing a *bepar fulphuris*, or fulphur united with an alkali, (in which form it is rendered foluble in water,) are diftinguished,

- 1. By their fætid smell, which resembles that of the scourings of a foul gun.
- 2. By their tarnishing the white metals, as filver, of a purple or black colour, and gold, of a deep yellow or copper colour.
  - 3. By their lactescence on the addition of acids, which by attracting the alkali precipitate the sulphur.
  - 4. By their turning a folution of sugar of lead of a brown colour, and by their vapours rendering visible characters wrote with the

above folution, which is the common sympathetic ink. The phlogiston which these vapours contain partly revive the metal in the saccharum saturni, and thus make the characters visible.

Sulphur dissolved in water by means of calcareous earth in a caustic state, (or quick-lime) exhibits none of the above signs of an alkaline hepar sulphuris. It is detected however, by the addition of alkali, which precipitates the calcareous earth, and by forming a true hepar sulphuris, the waters then begin to assume the qualities enumerated in the preceding paragraph.

## To discover Fossile Oil in Waters.

THIS is generally found floating on their furface, but may be blended with the water by means of an alkali, or quick-lime, in form of a foap.

Such waters will curdle on the addition of acids, just the same as hard waters do with soap.

# . To discover Calcareous Earth in Waters.

# THIS is soluble in water;

1. By being deprived of fixed air, or in the state of quick-lime, which is very well known from the manner of making lime water; from which the calcareous earth is again precipitated on restoring fixed air, as, e. g. in breathing into the water through a tube.

There is a quantity of fixed air generated in respiration \*, and this mode of trial may sufficiently serve; but besides this there is another method made use of—Fixed air produced from the effervescence of an acid with an alkali, or with chalk, may be received into a bladder and afterwards made to pass through the water to be examined in a gentle stream: if the water contains a calcareous earth, it will be precipitated, by the fixed air rendering it unsoluble.

<sup>\*</sup> Dr. Prieflly supposes that the fixed air produced in respiration is not thrown off from the lungs, but is precipitated from the common air by means of the phlogiston extricated in respiration.

The argillaceous, ochrey, and flinty earths can only be suspended or diffused, and cannot therefore constitute any impregnation in waters.

To discover Selenites in Water.

SELENITES, or gypfum, (vid. table of earthy falts,) which is the matter of all hard waters, is discovered,

- 1. By the well known effect of such waters in curdling soap.
- 2. By the evaporation of these waters thin laminous chrystals, like the scales of sishes, may be obtained, of a rough astringent taste, which are difficultly soluble.
- 3. By adding a folution of mercury in the nitrous acid a turbith mineral is formed, as before explained (vid. page 7.)

To discover Epsom Salts, and Magnesia, in Waters.

EPSOM SALTS, composed of the vitriolic acid and magnesia, (vid. table,) are obtained from waters by evaporation and chrystalliza-

tion, in the same manner as Glauber's salts, from which they are easily distinguished.

- 1. By the precipitation of magnefia on adding an alkali: Glauber's falts having no alkaline base suffers no decomposition.
- 2. By their not being fusible as Glauber's falts.

They are distinguished from common salt,

1. By giving out no fumes on the addition of oil of vitriol, (vid. page 7.)

### To discover Alum in Waters.

- 1. ALUM in waters shew many of the signs of an acid, (vid. page 16.)
- 2. By evaporating waters that contain an alum, they acquire a rough austere taste.
- 3. An alkali added to au aluminous water, precipitates the earth in *floculi*, or little curdled clouds, (not in a powder) which, if too much alkali be not made use of, will be redisfolved by the superabundant quantity of the vitriolic acid which alum contains.

To discover the Metallic Contents of Mineral Waters,

IRON:—The common tests of the prefence of iron are powdered galls, or tincture of galls in brandy, and the phlogisticated alkali \*. Waters containing iron, with the tincture of galls, strike a purple or black colour: sometimes the addition of a minute portion of alkali is necessary to make this experiment succeed. The trial with the phlogisticated alkali is a much more accurate and pleasing one; the waters which contain iron strike with this a beautiful Prussian blue.

Iron being distolved in waters by feveral different means, the same tests do not universally apply.

I. Waters which contain iron, dissolved by fixed air, drop it on the escape of the air;

<sup>\*</sup> The phlogisticated alkali, or Prussian alkali, as it is called, (because of its use in the manufacture of Prussian blue,) is made by the calcination of tartar and bullocks blood. The alkali of the tartar is thus charged with a quantity of inflammable matter, and is said to be phlogisticated.—For the explanation of the process by which Prussian blue is formed. Fid. Macquer's Distinguished Chemie.

hence the difficulty of transporting many of the chalybeate waters.

- II. Waters containing iron, diffolved by the volatile fulphureous acid, likewise quickly lose their properties by standing, but at first are to be tried as the following, viz.
- III. Those that contain a vitriol or iron, dissolved by the common vitriolic acid.

Martial vitriol in waters is afcertained,

- 1. By tincture of galls and phlogisticated alkali.
- 2. By alkali or calcareous earth, which precipitate an ochre.
- 3. By evaporation; fome waters, as Hart-fell, affording chrystals.
- IV. Waters that contain iron, by means of an hepar fulphuris, are known,
  - 1. By their fmell.
- 2. By their not depositing any ochre on the addition of alkali.
- 3. By their not affording chrystals on e-vaporation.

- V. Waters that contain iron by means of a calcareous hepar fulphuris;
  - 1. Afford no chrystals on evaporation.
- 2. Drop an ochre with caustic (though not with mild alkali) it will have no smell.

### To discover Copper in Waters.

- 1. THE Pruffian alkali precipitates copper, from waters containing it, in a red powder.
- 2. Volatile alkali, added to waters containing copper, gives them a fine blue or fapphire colour.
- 3. An iron wire immersed in a cupreous water is transmuted into copper; the vitriolic acid, which keeps the copper dissolved in the water, having a greater attraction for the iron, takes that up, and deposits the copper in its place \*.

<sup>\*</sup> It is faid that the waters of Wisklow in Ireland contain so much copper, that they obtain in this way a quantity sufficient to become an article of sale.

### To discover Zinc in Waters.

ZINC is precipitated from waters by the Prussian alkali, in the form of a white powder.

By proper evaporation chrystals of white vitriol may be obtained, for it is in the form of a vitriol, or dissolved by the vitriolic acid, that this semi-metal is found in waters.

#### SECTION II.

#### I. ON THE BATH WATERS.

HESE hot springs, situated in the east end of the island, were first discovered about the year 1695, and soon after being found to be a powerful remedy in the cure of the dry belly-ache and some other prevailing diseases of the climate, they were purchased by the country, with the adjacent lands, for the public use; an hospital was sounded for the reception of poor people, and it was the

object of the legislature, in order to make the place of the utmost possible benefit to the Island, to establish a township; accordingly commissioners were appointed, who were formed into a body corporate, vested with authority for granting of lands and making the necessary laws and regulations respecting the town and the bath. The public defign was much promoted by the zeal and liberal donations of some private gentlemen, particularly of Peter Valette, Esq. (whose public and benevolent character is too well known in this Island to require any Eulogium) and the place began to be visited, not merely on account of the falubrity of the waters, but as a fashionable sejour.

Nothing could have obstructed the progress of this town, or hindered the completion of the public plan, but the unfortunate political factions that prevailed in the country during its infant state; which destroying the harmony of private life, prevented the principal families from resorting here as formerly, and the place has since that time fallen into considerable decline. The House of Assemble.

bly has, nevertheless, not suffered the public to be deprived of the benefit of the waters by withholding any necessary grants for the keeping up of roads and buildings to make the place be conveniently visited by invalids; and the liberal fum they have lately given for these uses, it is hoped, will, by rendering the baths more convenient, and the place more agreeable, cause a greater conflux of company to it. There are besides many other circumstances that concur in inviting people to the place, and in removing the objections that were formerly made against it; amongst which I shall first mention the advantage of a better road, in consequence of the late turnpike act; next to that of the change of of climate, which was formerly, in this neighbourhood, fo exceedingly rainy as to be hardly habitable: the quantity of rain which has been known to fall in a given time, (to perfons not acquainted with the West-Indies, and have not seen what are called the feasons,) would seem incredible, above 40 perpendicular inches have fallen in about the space of 6 or 8 hours, which is nearly double the quantity that, on a medium, falls in Great-Britain through a whole year. The progress of cultivation having occasioned the falling of the adjacent woods, has produced a great alteration in the state of the seasons, particular years excepted, as the last, which was a very wet one over almost the whole Island.

Lastly, I must not omit to mention the Botanic Garden instituted here about sive years ago, which is already in a slourishing state, being stocked with a great variety of the most rare and useful plants collected from every quarter of the globe, and cannot therefore fail of furnishing out a great deal of entertainment not only to the cultivators of natural science, but to every one visiting the place.

## Analysis of the Bath Waters.

THE waters (for there are feveral springs) issue from sundry clefts and sissues in the rocks on the side of a small river, called from thence the Sulphur River, whose source is in that stupendous pile of mountains which run east and west through the Island: the several springs are situated very near to each other,

no others of the same nature having been discovered in the neighbourhood; in the parish of Portland indeed, (on the opposite side of the great ridge) there is a small one of the same kind, but of weaker impregnation, and lower temperature.

There appears to be no difference in the waters issuing from the several springs, except in their temperature, which is in some of them ten or twelve degrees less than in the principal one, which forms a current of nearly sour inches diameter, and supplies the baths on the opposite side of the river.

The water when received into a glass at the fountain side is perfectly transparent, but has a fætid sulphureous smell and taste. which it retains in some degree for several hours; this however ultimately slies off without any change or precipitation; and the water afterwards appears to be a very pure common water \*.

<sup>\*</sup> This water is extremely well fitted for bottling, and proves not inferior to Bristol water: The late Dr. M'Kenzie, who resided for some time at this place, had some of it by him in bettles for several years, which remained perfectly sweet and good.

The immediate effects which follow on drinking the bath waters are, frequent eructations of wind, fometimes a degree of Vertigo or head-ache, and fickness at the stomach; a copious flow of perspiration and urine; after which an exhibitantion of mind generally ensues, with an encrease of appetite, and at night natural rest.

# GRAVITY.

THE specific gravity of the water appears to vary a good deal from that of common water, as will be seen from the following experiments; when taken from the spring it is indeed lighter, on account of its heat and other causes, than common water, but cooled to the same point it becomes heavier, from the earthy and saline matter with which it is impregnated.

# EXPERIMENTS.

1. AN bydrometrical gauge plunged into the Bath waters, taken as hot as possible from the spring, sunk 4 inches 5-10ths.

- 2. The above mentioned instrument sunk in common water heated to the same 'point, (viz. about 125 deg.) only 3 inches 6-10ths.
- 3. The same gauge sunk in the Bath water, when cold, 1 inch 3-10ths.
- 4. The same gauge sunk in the river water 1 inch 5-10ths.

The Bath water is therefore to common water, when hot, as 45 to 36, when cold, as 13 to 15.

By weighing it as accurately as I could with a common beam, I found the gravity of the Bath water to exceed that of the river I drahm and 20 grains in the pint.

It feems extraordinary that the Bath waters should, when hot, be lighter than common water of the same temperature, and when cold, heavier; I can only explain it from the phlogiston which it contains, many waters become heavier after a decomposition takes place in their component principles: The Buxton waters, e. gr. placed in an exhausted receiver, gave out no air bubbles,

but turned whitish, and weighed 16 grains in the pint heavier immediately after, (vid. Monro on Mineral Waters).

### TEMPERATURE.

THE temperature of the feveral springs, so far as my observations have reached, is uniformly the same under all the differences of weather and variations of the atmosphere; though, if we may credit the experiments made by gentlemen some years ago, the water appears to have been hotter than I have ever sound it, and to have varied a few degrees in its temperature, at different times.

#### Heat of the main spring by my thermometer. 127 Ditto of the low fpring, 124 Ditto of the upper do. 114 Ditto of the highest do. 112 Ditto of the water running from the guttering into the baths, 122 Ditto of the water brought in a four gallon jug to the town, distant 118 nearly two miles,

It might be expected, that I should here explain the causes of heat in these springs, but the common hypothesis concerning the generation of hot waters is very unfatisfactory, and I shall not presume to offer any of my own: It may be fufficient to observe, that the heat of some waters is entirely adventitious, not owing to any principles which they contain, but acquired by passing through strata in the vicinity of volcanos or heated matters. Others appear to owe their heat either to some union or decomposition in the fossile matters through which the waters pass, and by which they become impregnated; the nature of this union or decomposition may be various, but has never been clearly understood, unless perhaps in the case of pyrites, on which the heat of the thermæ, or hot springs, is supposed most commonly to depend.

Experiments to afcertain the Contents of the Bath Waters.

### EXPERIMENT I.

HE Bath water, placed in the exhausted receiver of the air pump, gave out very few air bubbles.

Having no air-pump I could not make this experiment myself; but it was tried fome years ago by a medical gentleman \*, who anylysed the Mosfat Waters in this neighbourhood, and I believe with sufficient accuracy.

EXPERIMENT II. A bottle filled with the Bath water immediately from the fountain, had an oiled bladder tied over the mouth of it, after which it was placed in a vessel of hot water: The heat of the water being encreased to the boiling point, a small quantity of air was separated, which was secured by tying a ligature round the neck of the bladder, and afterwards made to pass in

<sup>- \*</sup> The account of this analysis is anonymous, but I am informed it was wrote by Dr. Mitchell, formerly a practitioner in Blue Mountain Valley.

a gentle stream through lime-water; but no precipitation ensued, as happened by breathing through the same lime-water (vid. p. 30.)

The Bath waters have been supposed to contain a considerable quantity of fixed air \*, but from what circumstance I cannot conceive, as they are totally destitute of that sparkling appearance and poignant taste that distinguish such waters, and the above experiments plainly demonstrate that they have no such impregnation.

EXPERIMENT III. A bottle accurately filled with the Bath water was inverted in a vessel fall of the same water, so as to allow no air to enter the bottle; the vessel with the water in this position was then placed over the fire, and the heat of the water encreased to the boiling point,—the water in the bottle was observed to descend about half an inch; but on suffering it to cool, it ascended again, so as to leave no vacuum in the bottle.

<sup>\*</sup> Vid. History of Jamaica.

EXPERIMENT IV. A bottle filled with the water was closely stopped by a cork, which was perforated by a crooked tube, the other end of which entered an inverted phial filled with water, and placed in a vessel of water after the manner of Dr. Priestly: Being allowed thus to remain for 24 hours, there was no descent of the water in the phial.

The two last experiments serve to shew that the Bath waters contain no air of any kind, unless a small quantity of common or atmospheric air, which I apprehend was what was extricated in experiment II. and III.—It is hence doubtful if the Bath waters contain any phlogisticated or inflammable air as has been supposed.

EXPERIMENT V. Some of the fine blue flowers of a convolvulus were infused for an hour or two in the Bath water without suffering any change in their colour; on adding a single drop of the oil of vitriol, the colour of the flowers was immediately changed from a blue to a bright red.

EXPERIMENT VI. Some drops of oil of tartar being added to a glass of the Bath water, no effervescence or other change enfued.

EXPERIMENT VII. Some drops of a folution of hepar fulphuris being added to a glass of the Bath water, no lactescence was produced, till I dropped in a little oil of vitriol.

EXPERIMENT VIII. Some drops of an unfaturated folution of lead in the nitrous acid, were added to a glass of Bath water \*, which effected no alteration.

EXPERIMENT IX. Some drops of a folution of mercury in the nitrous acid were added to a glass of the Bath water, no yellow precipitation ensued +.

From these experiments (N° 5, 6, 7, 8, 9,) it is very apparent that the Bath waters contain no vitriolic acid (vid. page 31) in a separate state.

<sup>\*</sup> See this experiment explained, page 34.

<sup>†</sup> Ditto do. do. page 37.

EXPERIMENT X. Some drops of the oil of vitriol were added to a glass of the Bath water, no ebullition or effervescence ensued.

In the account given of the Bath waters in the history of Jamaica, it is said, that acids dropped into the Bath water cause an ebullition; but it is certainly a mistake, and I believe it has arisen from the observer not rightly distinguishing between an ebullition and the dissicult mixture of the acid and the water; the acid, being so very ponderous, on being dropped into the water falls through it, and causes an appearance that might be mistaken for an effervescence, by persons not properly acquainted with the subject.

EXPERIMENT XI. A folution of fal martis being dropped into the Bath water, no ochrous precipitation followed, (vid. p. 35, fec. 4.)

EXPERIMENT XII. Some drops of a nicely faturated folution of chalk in the nitrous acid were added to a glass of Bath water, but no precipitation ensued, (vid. p. 35, sec. 3.)

These experiments, (N° 10, 11, 12,) clearly shew that there is no alkali in the Bath water, (vid. p. 35.) but lest the alkali might be in too diffused a state to be discovered by the above tests, I repeated the experiments on the water after considerable evaporation, and the result was the same.

EXPERIMENT XIII. To the Bath waters I added a small portion of alkaline salt, and observed no change, but the same experiment being tried, after evaporating the water a little, a white precipitation followed, (vid. p. 14.)

EXPERIMENT XIV. A few drops of a faturated folution of lead in the nitrous acid, added to the Bath water, caused a milkiness, (vid. p. 14.)

The same effect followed on adding a clear solution of saccharum saturni.

EXPERIMENT 15. The water during evaporation, with a very gentle heat, deposited a quantity of reddish brown earth, which I separated by decanting the liquor from time to time as it collected at the bottom of the vessel. EXPERIMENT XVI. To the earthy precipitate obtained in the preceding experiment, I added some distilled water, but only a part of it dissolved.

EXPERIMENT XVII. To the foregoing precipitate repeatedly washed in fresh quantities of distilled water, I added some drops of the oil of vitriol, which caused a slight effervescence; but great part of it remained undissolved, which was also insoluble in the nitrous acid, and with difficulty soluble in water.

EXPERIMENT XVIII. After further evaporation of the water I placed it at rest for
12 hours, and then found it covered with
thin laminous chrystals like the scales of
sishes, which being taken off and put in distilled water, great part of them continued to
sloat therein, remaining undissolved for some
days: the taste of these chrystals was rough
and earthy, not faline. These are the properties of the selenitic compound (vid. p. 8);
which the following experiment more clearly demonstrate them to have been.

EXPERIMENT XIX. To a folution of the chrystals (exp. 18) in distilled water, I added some drops of the solution of mercury in the nitrous acid, which caused a yellow precipitation (vid. p. 37, sec. 5.)

EXPERIMENT XX. That portion of the earth which was dissolved by the vitriolic acid in experiment 15, was precipitated again by adding a few drops of oil of tartar. I washed the precipitate in distilled water, and then re-dissolved it in fresh vitriolic acid; the liquor formed thereby was bitter and saline, resembling that of epsom salts.

I repeated this folution and precipitation feveral times, so as to leave no doubt of the earth being a magnesia.

The foregoing experiments made on the earth precipitated during evaporation, were all repeated on the refiduum left after evaporation to drynefs, with nearly the fame refult, only that I found it difficult to obtain the earth entirely pure, fome of the faline matter adhering, notwithstanding repeated affusions of distilled water.

Magnesia in waters is generally combined with the vitriolic acid, constituting epsom salts; but as there are no signs of vitriolic acid in this water, unless in the selenitic compound, it is not improbable that the magnesia is blended with the sea salt, which this water appears, from the subsequent experiments, to contain, forming with the muriatic acid a fixed ammoniac (vid. p. 8. sec. 3.)

EXPERIMENT XXI. On dropping a folution of filver in the nitrous acid into the Bath water, a white curdled precipitation immediately took place, (vid. p. 38. fec. 4.)

EXPERIMENT XXII. The precipitate in the preceding experiment, with a little tartar, being rubbed on polished brass, gave it, by the assistance of heat, a silver colour \*.

Having these evident proofs, (experiment 20, 19,) of the presence of muriatic salt, I endeavoured to obtain it in its chrystallized state.

EXPERIMENT XXIII. A quantity of the refiduum was disfolved in distilled water,

<sup>\*</sup> This precipitate called a Luna Cornea is the substance made afe of by artists for some kinds of silvering.

and the liquor decanted clear from the earthy fediment, which was then flowly evaporated, first bythe fire, and then by the sun. Regular cubical chrystals were thus obtained, having all the properties of common salt, (vid. p. 37.)

EXPERIMENT XXIII. A portion of the residuum (experiment 15,) being thrown on a hot iron, gave out no summes or smell of sulphur.

EXPERIMENT XXIV. The incrustation adhering to the rocks about the spring was also burnt, but yielded no proofs of its containing any sulphur.

EXPERIMENT XXV. A new coined bright dollar was placed in the water at the place of its issue, which in a few minutes was tarnished of a deep purple colour,—a bright piece of gold coin was turned of a deep copper colour. The same trials being made at the extremity of the gutturing, where the water is discharged into the Baths, the metals were but slightly tarnished after lying a considerable time.

EXPERIMENT XXVI. Having made certain characters on paper with the sympathetic ink, (i. e. a solution of saccharum saturni in water) I tied the paper over a broad mouthed bottle filled with the Bath water, the vapours of which soon rendered the characters visible.

EXPERIMENT XXVII. Saccharum faturni disfolved in the Bath water causes no red or brown precipitation.

These experiments (N° 23 and 24) prove that the Bath waters contain no actual sulphur (vid. p. 39); but the following ones (N° 25 and 20) evidently shew the presence of the phlogiston in some form (vid. p. 40): Why experiment 27 does not succeed I cannot tell, unless from the phlogistic principle being so very volatile as not to remain long enough to produce the effect.

The fætor of these waters indicate the presence of a hepar sulphuris (vid. p. 40); but this is rendered doubtful by the experiments made with acids (vid. experiment 10) which cause no precipitation, and others shewing that the waters contain no alkali.

From what has been faid (vid. p. 41) concerning hepar fulphuris with quick-lime, it is obvious that fulphur cannot be fuspected in the Bath waters, in this form.

In what state of combination then, are we to suppose the phlogiston existent in these waters? According to the late discoveries, respecting the various species of phlogisticated air, it seemed exceedingly probable that it was in some such form: This opinion seems, however, overturned by experiment 2d and 3d, in which I sound it impossible to obtain any air that was permanent.

The mode of combination must still remain a desideratum, as chemistry has not, that I know of, found out any other methods of trial for ascertaining it.

Before I dismiss this subject I must not omit taking notice of Dr. Brown's hypothesis concerning these waters, (vid. the Natural History of Jamaica) which is, that they contain the volatile vitriolic acid connected with a calcareous earth: they certainly contain

fpecting the phlogiston. Besides, how the volatile acid can be supposed combined with the calcareous earth, I do not conceive; for selenites is one of the most fixed salts we know of. As he has taken no notice of any of the other contents of these waters, which were very obvious on the slightest trial, I suspect that he never made any experiment on them, but spoke merely from conjecture.

EXPERIMENT XXVIII. Into a glass of the Bath water I dropped a small quantity of the tincture of galls in brandy; no apparent change took place after standing some time, till I added a solution of iron, when it immediately assumed a deep purple colour.

EXPERIMENT XXIX. I repeated the foregoing experiment, using, instead of the galls, the phlogisticated alkali; but no effect followed till I added the iron, when the usual beautiful blue precipitation immediately took place (vid. p. 45.)

It is hence (viz. from N° 28 and 29) obvious, that these waters have no metallic impregnation, though they have been generally supposed to contain some iron; and Mr. L—— (vid. Hist. Jamaica) says, that there is an ochrey precipitation about the rocks over which the waters run. The yellow slimy incrustation about the rocks may have something of the appearance of an ochre, but from the following experiment it does not seem to contain any iron.

EXPERIMENT XXX. I took a quantity of the above mentioned slimy matter, adhering about the rocks where the spring is, which having first dried in the sun, I mixed with oil and charcoal dust, and placed it in the strong heat of a furnace for some hours; a blackish gritty powder was found in the crucible, which was not in the least affected by the magnet,

EXPERIMENT XXXI. I then subjected it to the fire without any admixture, suspecting that it was of a vegetable origin, and would yield a pot-ash; after keeping it for a considerable time in a very violent heat, I obtained a powder resembling brick dust,

reddish and gritty; a part of this powder effervesced with acids and dissolved, but most of it retained its gritty form. Pot-ash being at first in a caustic state, this experiment must not be tried immediately after removing it from the surnace, unless you throw in fixed air to the water you mix it with.

I infer from the foregoing experiment, (N° 31) that the slimy matter of the rock is partly of a vegetable nature, produced by the putrefaction of leaves, &c. falling into the water, and partly stoney, some particles of sand and rock being entangled in it.

EXPERIMENT XXXII. On the Rock.—
The rock being kept for some time in a strong heat, was partly converted into quicklime.

EXPERIMENT XXXIII. The rock powdered and mixed with charcoal, &c. as in experiment 30,—shewed no signs of iron; some of the iron ore in the neighbourhood being tried in the same manner, was afterwards attracted very strongly by the magnet

Having thus related and explained my feveral experiments made on the Bath waters, I shall next, after summing up the results in a general table, proceed to shew their effects on the human body, and their cure in diseases.

## Table of Experiments and Refults.

EXPERIMENTS.

RESULTS.

Nº 1, 2, 3, -	% No fixed air.
I, 2, 3, 4, -	No inflammable air.
- 5, 6, 7, 8, 9,	No separate acid.
- 10, II, I2, -	No separate alkali.
<b>—</b> 13, 14, 15, 16,	Ba
17, 18, -	A selenetic salt.
20,	Earth of magnefia.
- 21, 22,	Common marine falt.
- 23, 24,	No actual fulphur.
- 25, 26,	Agood deal of phlogiston
10, 11, 12, - j	No hepar sulphuris.

#### CHAPTER IV.

On the Effects and Uses of the Bath Waters.

TAVING learned by analysis the matters contained in mineral waters, we can fometimes with certainty determine, a priori, what will be their effect on the human body; but not univerfally; for notwithstanding the several principles of a water may be clearly detected, yet their mode of combination being unknown; their uses can only be conjectured, till experience has ascertained them. The Somersetshire Bath Waters, e. g. contain, according to the latest and best analysis by Dr. Faulkener and others, a little common falt, some bepar sulphuris with quick-lime, a minute portion of iron, (viz. only one 37th of a grain in a pint of the water) some selenites and fixed air. However active these principles may be, I apprehend it will be impossible, from the small proportion they contain of each, to account fully for their extensive influence in the cure of diseases. There will be as much difficulty in accounting fatisfactorily for the operation

of our waters; yet from comparing their effects together, their general action seems to be fimulant; which power they owe chiefly to the sulphureous gas, or phlogistic principle, the fixed contents being in too small a quantity to be productive of any material operation.

That the Bath waters act as a stimulant is very obvious from the immediate effects which the drinking of them produce, viz. eructations of wind, vertigo, head-ache, and fever, &c. &c. (viz. p. 53) as well as from the nature of several diseases in which they are found remedial.

Dr. Brown, in his Natural History of the Island, says of these waters, "that they are "remarkably beneficial in all capillary obstructions or disorders proceeding from weakness or the want of proper glandular fecretions; in all lentors or viscidities proceeding from the inaction of the solid system; in consumptions, nervous spasses and weaknesses: They restore the appetite and usual action of the viscera, invigorate

"the circulation, warm the juices, open the fkin and urinary passages, strengthen the nerves, and seldom fail of producing easy fleep at night.

Mr. L \* \* \* \*, in his well wrote History of the Island, gives nearly the same account of these waters;—He says, " they
"excite appetite, promote urine, produce
"sleep, cure ulcers, strengthen the nerves,
"and cure palsey.

These effects, most of which I have seen verified in a great number of cases, evidently indicate a stimulant power. 1stly, The expulsion of statulencies, increase of appetite, &c. shew that the water excites the action of the stomach. 2dly, The vertigo, head-ache, and sever, which they sometimes induce, are consequent on an encreased circulation. 3dly, Their diuretic effects, in like manner, proceed from their stimulant action on the kidneys: their operation in this respect, is in part owing to the quantity taken in as a diluent, but they have certainly a further effect than as a mere diluent; for in some

greatly exceeded the whole quantity of fluid made use of. 4thly, An increase of perspiration may be variously accounted for; 1stly, the waters may prove diaphoretic from their action in the stomach, between which and the extreme vessels of the body there is a particular consent: 2dly, They must be diaphoretic as being diluent; but besides, they may, 3dly, from their sulphureous contents, act as a stimulant in the extreme capillary vessels.

Whether the Bath waters may not also have fome alterant and antispasmodic power, I shall not determine, but it would seem probable that they are possessed of both.

Having faid thus much to explain the general nature and action of the Bath Waters, I shall now consider their uses in particular diseases.

I. The Dry Belly-ache feems to have been the complaint in which the good effects of the Bath waters were first most eminently ex-

<sup>\*</sup> I am obliged to my friend Dr. Clarke for a very particular case of this nature.

perienced, and they have ever fince been applied to as a most sovereign remedy against the paralytic torpor and relaxation that fupervene to the excruciating spasms which by turns affect the bowels and limbs of people in this horrid disease. I must not in this place enter largely into the confideration of either the causes or cure of this complaint; but whatever it depends on, whether on the action of any poison taken in (as of lead, acid, ardent spirit, &c.) on an acrimonious bile in the first passages, or on a constriction of the furface from cold, concurring with an irritable state of the bowels, it is obvious, that, after removing the constipation, the principal indication of cure is to restore the lost tone. As spasm, or a violent state of contraction in the muscular fibres, produces the alternate state of atonia or relaxation, so vice versa, atonia gives occasion to the return of spasm: Accordingly we see that patients, once affected with this disorder, are subject to frequent relapses, which nothing can so effectually prevent, as exciting the action of the intestinal canal. With this view various medicines are employed, but the

Bath waters have been found, of all others, the most useful remedy: Their effects in such cases seem almost miraculous.

The use of the Hot Baths jointly with the waters, 1st, by the grateful stimulus they impart to the nervous system, and, 2d, by causing a free determination to the surface, contribute greatly inremoving the torpor and palsey of the extremities.

II. Genuine Palsey, or Hamiblegia, is a a disorder totally of a different nature from the preceding. There is in this case an affection of the brain, or of the nerves in their origin; but notwithstanding such a dissimilitude, the Bath waters may, in conjunction with other remedies, prove extremely beneficial. A remarkable instance has lately occurred of the efficacy of the Bath waters in paralytic diforders,-A gentleman under recovery from a long fever, by exposure to cold air, fuddenly loft the use of all his limbs; Having tried the use of several remedies with little effect, he had recourse to the Bath waters, by which he was in a few weeks perfectly recovered.

- III. The use of the Bath waters is highly conducive to convalescents of every class, especially after fevers: By exciting appetite and invigorating the bowels, it restores the tone of the whole system, and obviates a tendency to relapse.
- IV. The effects which the Bath waters have on the nervous system, and in affisting the functions of the stomach, shew them to be a very fit remedy in all bysterical and sexual complaints.
  - V. I shall next consider how far the Bath waters are useful in visceral obstructions, or in complaints of the liver and spleen; patients labouring under these complaints have frequently had recourse to these waters, and, I believe, have not always been disappointed of receiving benefit, but I nevertheless think that in such complaints they are rather an ambiguous remedy: So far as they strengthen the functions of the stomach and the bowels they may be useful, but from their stimulant or heating quality, they may semetimes do hurt by exciting inflammation. Persons who

have undergone a mercurial regimen for the removal of these complaints, may, however, derive great advantage from the waters: The danger of topical inflammation being removed, the use of them will afterwards contribute much to their recovery. This leads me to speak of their effects after salivation in other disorders.

VI. Mercury, though the only certain remedy which some diseases admit of, is nevertheless an hazardous one; under the most careful management it sometimes makes great depredations in the constitution, particularly in warm climates, where the tone of the fystem being once impaired, is difficultly recovered. In this view, and for removing fome fymptoms, which mercury of itself is not a cure for, the Bath waters are highly beneficial in the lues venerea: They ferve to support the general health, and perhaps affist in washing out the venereal virus. With the Hot Baths they are of great use in relieving the nocturnal pains, cleaning and curing the ulcers, eruptions, &c. &c.

They have in some instances discovered a singular efficacy in stopping old gleets \*. They may operate in two ways in the cure of such complaints; 1st, as a diluent in washing out some latent virus; or, 2dly, by their tonic power in the stomach, and in bracing up the whole system. It is, however, immaterial how they act, if they produce the effect, which is unquestionable: I have no doubt of their proving equally so in the fluor albus.

VII. The Bath waters are not only ferviceable in the lues venerea, but also in that more loathsome distemper of negroes, the yaws: By the drinking of the waters, and the use of the hot baths, the eruption is thrown out more plentifully on the surface of the body, and the matter eliminated; by which the internal system seems to be relieved, and the cure expedited. Nothing can be more pernicious than the general practice of negroes in this disorder, I mean

<sup>\*</sup> Dr. Irvine, a gentleman univerfally known for his many virtues, as well as by his long refidence in this neighbourhood, has favoured me with a very fingular case of this kind, where a perfon was cured by the Bath waters of a gleet of eleven years stands lag.—I know of some other cases almost as singular.

that of washing in the cold rivers. The surface being by that means constringed, the yaws are repelled, which I believe is frequently the cause of subsequent bone-ache and distortion.

VIII. Every kind of cutaneous distemper may receive advantage from the Bath waters. An inveterate leprosy was relieved by it; but I apprehend that in cutaneous descedations there may be found waters still more useful than those of the Bath. Their use in absterging and drying up foul ulcers, is so well known I shall say nothing on the subject.

IX. Dr. Brown mentions confumption among the diseases in which the Bath waters are useful; but if he means a consumption of the lungs, I should fear he is mistaken: Considering the degree of phlogistic diathesis, or inflammatory disposition that prevails in this disease, I conceive the Bath waters may rather tend to aggravate than relieve the symptoms; but I have no experience, and have not been able to collect any facts on the subject.

X. I should not either suppose the Bath waters indicated in dropsy, but a cure in that disorder has been obtained by such various and even opposite means, that I should not think the trial of them improper where other remedies have failed. The Bath waters being possessed of an active principle, capable of producing material changes in the system, may accidentally excite the action of the absorbent vessels, and cause the waters to be carried off by the different outlets of the body:

XI. In the *jaundice* they are useful after the obstruction in the biliary ducts is removed, for carrying off the bile in the circulation, and for strengthening the impaired functions of digestion, &c.

XII. The diuretic effect of the Bath waters make them useful in nephritic complaints, in which they operate both as a diluent and by a specific quality without much stimulus. In such nephritic affections as depend on a gouty diathesis, the Bath waters are calculated to answer extremely well;

which will be obvious from what I have to remark on their effects in the gout.

XIII. The gout is a disease depending not on a morbid matter, as has been commonly supposed by physicians as well as others, but on a certain state of the moving fibres, which belongs to a particular temperament or constitution that is frequently hereditary, being transmitted from father to fon in the same way as a likeness of features and other constitutional peculiarities: Hence there is no cure to be obtained in the gout but by obviating the effects of this particular temperament, which is only done in one way, viz. by exercise and abstinence from animal food. The disease, as an articular affection, seems falutary, tending to preserve the constitution; but when it becomes irregular and misplaced, it is then dangerous and destruct-Every case of irregular and misplaced gout probably depends on the want of a neceffary degree of tone in the stomach, to determine the affection to the extremities. We from hence see how the Bath waters are serviceable in the gout. The waters and hot

baths, by exciting the action of the stomach, and of the extreme vessels, call back the gout to the joints, after being repelled, or determine it there, when wandering about the body.

When the constitution is much debilitated, and the gout occasions affections of the head and stomach particularly, instead of producing inflammation in the joints, it is called atonic; that is, from the want of tone the disease which should be seated in the extremities seizes on other parts, or is not able to form in the joints. In cases of this nature the Bath waters are very beneficial.

The inhabitants of the West-Indies make frequent voyages to Great-Britain on account of health when perhaps they have a remedy nearer at hand. In the atonic gout Dr. Cullen recommends a warm climate, and I therefore embrace the opportunity of suggesting to Jamaica gentlemen residing in Great-Britain, that under this disease they have in their own Island a climate more propitious, and in the Bath waters a remedy not less efficacious, and

which deserved to be no less celebrated that those of England.

I might go on to illustrate the effects of the Bath waters in a variety of other diseases, but I shall take notice of only one more, viz.

XV. Chronical rheumatism, which fignifies, habitual pains affecting particularly the large joints of the body without much fever, and fometimes with little fwelling, but with debility and coldness of the affected part. Rheumatic affections are the complaints of people in cold climates; but the inhabitants of the West-Indies are not exempt from them. Exposition to rain, night dews, and the north winds that blow at a particular feafon of the year, occasion such disorders, that are apt, notwithstanding every care and attention to medicine, to return and become chronical. The Bath waters stand very much recommended in fuch cases, though at first they feem to aggravate the difease, the pains being for some time exasperated: By perseverance, however, the patient is fune of obtaining relief.

Having, as I presume, said enough to shew the general utility of these Bath waters, and to direct to the use and application of them; nothing remains but to make a few remarks on the method of using them.

Rules for the drinking of mineral waters can only be general; they are nevertheless of use. The following ones are such as I think more particularly require attention.

- I. To begin the use of the waters with small draughts, which may be repeated at short intervals, as the sudden ingurgitation of a large quantity may sometimes cause uneasiness and bad effects, (vid. p. 53.)
- II. To use now and then a gentle laxative as occasion may require, to prevent a constipated state of the bowels.
- III. To drink them as nearly to the fountain or place where they iffue, on account of the extreme volatility of their medicinal principle, which is fo remarkable that it is comparatively of little use to drink them at any

distance; they lose even in their transportation across the river \*, (vid. p. 66, sec. 4.)

IV. To continue the use of them for a due length of time.

The character of any medicine being established, people are commonly disposed to expect too much from it. There are instances where the effects of the Bath waters have been manifested very suddenly, but in some chronical cases it is requisite they should be persisted in for some length of time: Patients, after having despaired of obtaining any relief, have, by perseverance, obtained a persect recovery from the most inveterate diseases.

V. To use the hot baths in the afternoon rather than in the morning, as they tend to procure ease and sleep: Care should be nevertheless taken to avoid cold on returning from the Baths, and they ought not to be used too soon after meals.

<sup>\*</sup> The inconvenience which at prefent attends getting to the fpring will be from removed by a bridge that is to be built across the river.

VI. Lastly, as to regimen.—I know of no particular one required by the Bath waters. It has been customary to avoid wine and fruits, not as I apprehend, from any disagreement these have with the waters, but because they have not been suited to the complaints for which the waters were drunk: A little wine may be sometimes very necessary, but in general it is better totally to relinquish it, as the precise limits are difficult to be ascertained, and as it may interfere with the use of the waters.

That I may omit nothing that can be of use in directing to the application of these waters, I shall here subjoin a catalogue of all such diseases as they are likely to prove beneficial in.

" Quot et quam diversi morbi curentur,
